Wats4000 up and running

The directories that I am seeing are a list of files that act as backbone/structure to the website that one can start building of.

The vue app is defined in the style editor as a markdown with script and style in the src directory.

The package.json contain set of structure data that handle other data (incoming data).

The node_modules directory contain JavaScript files.

The direction for the scripts run with npm run is in the readme.md file

Dependencies in package.json file are modules that are required at time of deployment of the app while devdependencies are modules that are used only during the building/development of the app.

The doc directory contain the CSS file of the app.

The static filenames seem to require having the 'app' in the name of the file in order for it to execute?

I can't see the full contents of the CSS and JS files, those contents are at the server end?

The general purpose of each of the config files is to acquired modules to the app.

When the npm run build command is executed the app files from both CSS and JS are executed to get the app ready for runtime deployment that follow by npm run serve command to enable the app to host locally? The files are gathered from the server to the user end to serve the deployment of the app.
